Single Instruction, Multiple Data (SIMD): A single operation (task) executes simultaneously on multiple elements of data. The number of elements in a SIMD operation can vary from a small number, such as the 4 to 16 elements in short vector instructions, to thousands, as in streaming vector processors.

A complex instruction set computer (CISC / 'sɪsk /) is a computer in which single instructions can execute several low-level operations (such as a load from memory, an arithmetic operation, and a memory store) or are capable of multi-step operations or addressing modes within single instructions. The term was retroactively coined in contrast to reduced instruction set computer (RISC) and has therefore become something of an umbrella term for everything that is not RISC, from large and ...

Each core can execute only one instruction at a time, however it's so fast it seems as if you are running multiple threads simultaneously. Threads that have messages waiting in the queue, are put into the "active pool" which uses the first in, first out prioritization technique in order to arrange which instruction should be called first.

How can a single core processor run multiple tasks at once?

A complex instruction set computer (CISC /pronounce as 'sɪsk'/) is a computer where single instructions can execute several low-level operations (such as a load from memory, an arithmetic operation, and a memory store) or are capable of multi-step operations or addressing modes within single instructions, as its name suggest "COMPLEX INSTRUCTION SET".

Multiprocessing can refer to one job using several processors to execute sets of instructions in parallel. False When a programmer indicates in the code which instructions can be executed in parallel in a program (for example, using COBEGIN and COEND), it is called implicit parallelism.

A superscalar processor is a CPU that implements a form of parallelism called instruction-level parallelism within a single processor. In contrast to a scalar processor that can execute at most one single instruction per clock cycle, a superscalar processor can execute more than one instruction during a clock cycle by simultaneously dispatching multiple instructions to different execution units on the processor.

Also, in batch files, this feature can be used to put several commands on one if statement, as in this example: if not exist list.dat dir c:\in >list.dat & dir c:\out >>list.dat. If the file list.dat does not exist, then CMD runs the two dir commands in turn. This can simplify the batch program. There are two other ways to specify multiple ...

Normally each statement is written on separate physical line in editor. However, statements in a block can be written in one line if they are separated by semicolon. Following is code of three statements written in separate lines. a=10 b=20 c=a*b print (c) These statements can very well be written in one line by putting semicolon in between.

There is no such thing as a single thread running on multiple cores simultaneously. It doesn't mean, however, that instructions from one thread cannot be executed in parallel. There are mechanisms called instruction pipelining and out-of-order execution that allow it.
